1. What does a neuron compute?

A neuron computes a function g that scales the input x linearly (Wx + b)

### Correct

Correct, we generally say that the output of a neuron is a = g(Wx + b) where g is the activation function (sigmoid, tanh, ReLU, ...).

- A neuron computes an activation function followed by a linear function (z = Wx + b)
- A neuron computes the mean of all features before applying the output to an activation function

2. Which of these is the "Logistic Loss"?

$$\mathcal{L}^{(i)}(\hat{y}^{(i)}, y^{(i)}) = -(y^{(i)}\log(\hat{y}^{(i)}) + (1 - y^{(i)})\log(1 - \hat{y}^{(i)}))$$

# This should not be selected

No. This one is the L2-loss

 Suppose img is a (32,32,3) array, representing a 32x32 image with 3 color channels red, green and blue. How do you reshape this into a column vector?

1/1 point

- x = img.reshape((1,32\*32,\*3))
- x = img.reshape((3,32\*32))
- x = img.reshape((32\*32\*3,1))

Correct

x = img.reshape((32\*32,3))

4. Consider the two following random arrays "a" and "b":

1/1 point

```
1 a = np.random.randn(2, 3) # a.shape = (2, 3)
2 b = np.random.randn(2, 1) # b.shape = (2, 1)
3 c = a + b
```

c.shape = (2, 3)

#### Correct

Yes! This is broadcasting. b (column vector) is copied 3 times so that it can be summed to each column of a.

c.shape = (3, 2)

c.shape = (2, 1)

The computation cannot happen because the sizes don't match. It's going to be "Error"!

5. Consider the two following random arrays "a" and "b":

1/1 point

```
1 a = np.random.randn(4, 3) # a.shape = (4, 3)
2 b = np.random.randn(3, 2) # b.shape = (3, 2)
3 c = a*b
```

What will be the shape of "c"?

#### Correct

Indeed! In numpy the " $\star$ " operator indicates element-wise multiplication. It is different from "np.dot()". If you would try "c = np.dot(a,b)" you would get c.shape = (4, 2).

c.shape = (4,2)

c.shape = (4, 3)

c.shape = (3, 3)

G. Suppose you have  $n_x$  input features per example. Recall that  $X=[x^{(1)}x^{(2)}...x^{(m)}].$  What is the dimension of X?

1/1 point

 $(n_x, m)$ 

Correct

 $\bigcirc$  (1,m)

 $(m, n_x)$ 

(m,1)

7. Recall that "np.dot(a,b)" performs a matrix multiplication on a and b, whereas "a\*b" performs an element-wise multiplication.

1/1 point Consider the two following random arrays "a" and "b":

```
1 a = np.random.randn(12288, 150) # a.shape = (12288, 150)
2 b = np.random.randn(150, 45) # b.shape = (150, 45)
3 c = np.dot(a.b)
```

What is the shape of c?

The computation cannot happen because the sizes don't match. It's going to be "Error"!

#### Correct

Correct, remember that a np.dot(a, b) has shape (number of rows of a, number of columns of b). The sizes match because :

"number of columns of a = 150 = number of rows of b"

- c.shape = (150,150)
- c.shape = (12288, 150)

8. Consider the following code snippet:

```
1 # a.shape = (3,4)

2 # b.shape = (4,1)

3

4 * for i in range(3):

5 * for j in range(4):

6 c[i][i] = a[i][i] + b[i]
```

How do you vectorize this?

- c = a + b
- c = a.T + b.T
- c = a + b.T

Correct

c = a.T + b

Consider the following code:

```
1 a = np.random.randn(3, 3)
2 b = np.random.randn(3, 1)
3 c = a*b
```

What will be c? (If you're not sure, feel free to run this in python to find out).

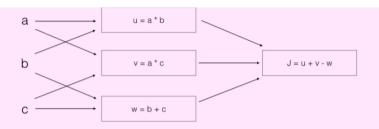

This will invoke broadcasting, so b is copied three times to become (3,3), and  $\ast$  is an element-wise product so c.shape will be (3, 3)

# Correct

- This will invoke broadcasting, so b is copied three times to become (3, 3), and \* invokes a matrix multiplication operation of two 3x3 matrices so c.shape will be (3, 3)
- This will multiply a 3x3 matrix a with a 3x1 vector, thus resulting in a 3x1 vector. That is, c.shape = (3,1).
- It will lead to an error since you cannot use "\*" to operate on these two matrices. You need to instead use np.dot(a,b)

What is the output J?

$$J = (c - 1)*(b + a)$$

$$\int J = (a - 1) * (b + c)$$

# Correct

Yes. 
$$J = u + v - w = a*b + a*c - (b + c) = a*(b + c) - (b + c) = (a - 1)*(b + c).$$

$$\int a^*b + b^*c + a^*c$$

$$J = (b - 1) * (c + a)$$
